Familial Adenomatous Polyposis syndrome: Information for families with a pathogenic variant in the \textit{APC} gene

The purpose of this handout is to give you detailed information about your genetic test result which you may read and discuss with your medical providers. Researchers will continue to study the \textit{APC} gene, so please check in with your medical providers once a year to learn of any new information that may be important for you and your family members. (Please see the last page for a glossary of medical terms which are underlined in this document.)

You have a pathogenic variant in the \textit{APC} gene. This means you have Familial Adenomatous Polyposis syndrome (also known as FAP syndrome).

What is hereditary cancer?

- Cancer is a common disease. One out of every 3 people in the United States will develop some type of cancer in his or her lifetime.

- About 5-10\% of cancers (up to 1 in 10) are hereditary. A hereditary cancer occurs when a person is born with a pathogenic variant (also known as a mutation) in a gene that increases the chance to develop certain types of cancer. A pathogenic variant can be passed on from one generation to the next.

- Typically, families with FAP syndrome have one or more of the following features:
  - Colon cancer diagnosed at a young age.
  - Many colon polyps (also called polyposis), typically 100’s to 1000’s of polyps.
  - Multiple family members with colon polyposis and/or colon cancers.

What is a pathogenic variant?

- DNA is our genetic material which is passed on from parent to child. It contains the instructions for how our bodies develop, grow, and function. A gene is a small piece of DNA which has a specific job to do in the body. Some genes determine features like eye color or height, while other genes are involved with our health.

- We all have variations in our genes that make us different from one another. Most of these variations do not change the way our genes work. However, some variations do prevent a gene from working correctly. This type of variation is called a pathogenic variant or mutation.

Why does having this pathogenic variant cause an increased risk for cancer?

- The job of the \textit{APC} gene is to prevent cancer. It is called a tumor suppressor gene. When working correctly, tumor suppressor genes help to prevent cancer by controlling the growth and division of cells.

- People born with FAP syndrome have only one working copy of the \textit{APC} gene, so their risk for cancer is higher than average.

What are the cancer risks linked to this pathogenic variant?

- People born with FAP syndrome also have a higher risk for pre-cancerous polyps in the colon, called adenomas. An adenoma is a growth that, if not removed, can grow into a colon cancer.

- People with FAP syndrome have higher risks for certain types of cancer which are outlined in the table below.
Table: **Lifetime Cancer Risk** (chance to get cancer at any time during life)

<table>
<thead>
<tr>
<th>Cancer Type</th>
<th>People who do not have FAP syndrome</th>
<th>People who have FAP syndrome</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colon cancer</td>
<td>4-5%</td>
<td>Nearly 100% (without surgical intervention*)</td>
</tr>
<tr>
<td>Small intestinal (duodenal) cancer</td>
<td>&lt;1%</td>
<td>4-12%</td>
</tr>
<tr>
<td>Pancreatic cancer</td>
<td>1-2%</td>
<td>Possible increased risk</td>
</tr>
<tr>
<td>Papillary thyroid cancer</td>
<td>1%</td>
<td>&lt;2%</td>
</tr>
<tr>
<td>Hepatoblastoma (liver) cancer</td>
<td>&lt;1%</td>
<td>1.2-2% (usually &lt; 5 years of age)</td>
</tr>
<tr>
<td>Stomach cancer</td>
<td>&lt;1%</td>
<td>0.5-1.3% in Western cultures</td>
</tr>
<tr>
<td>Medulloblastoma (brain cancer)</td>
<td>&lt;1%</td>
<td>Slightly increased</td>
</tr>
</tbody>
</table>

*These risks are based on people who did not have regular screening and/or other treatments such as risk-reducing surgery.

- Not all families/individuals have the exact same degree of risk, which is why some numbers are shown as a range. Risks may be affected by the environmental factors, lifestyle, personal medical history, family cancer history, and other genetic or unknown factors.

- In addition, people with FAP may also have non-cancerous features such as: bony growths known as osteomas (typically in the jaw or skull), dental problems (such as extra teeth or dental tumors), unusual pigmentation in the eye which does not cause vision problems (CHRPE), gastric fundic gland polyps and soft tissue tumors (epidermoid cysts, fibromas and desmoid tumors).

**Is it possible to fix the pathogenic variant?**

Unfortunately, it is not yet possible to fix a pathogenic variant in the APC gene. However, it is possible to change your medical care and certain things in your lifestyle. Your provider(s) will work with you to discuss these options and create a medical care plan that is right for you.

**What are the medical care recommendations?**

The medical care recommendations for people with FAP syndrome are divided into three categories: surveillance, surgery, and medications.

**Surveillance:**

The purpose of surveillance (also referred to as ‘screening’) is to diagnose cancer at as early a stage as possible. Although scientists and physicians can’t prevent a cancer from developing, early detection is important. When a cancer is detected early, it is more likely to be treated successfully. There are very good surveillance methods for some, but not for all types of cancer.

The table below outlines surveillance recommendations for individuals with FAP syndrome (adapted from the National Comprehensive Cancer Network Genetic/Familial High-Risk Assessment: Colorectal Guideline, Version 1.2020). Please note that these are general guidelines. Specific guidelines for individual patients and families may differ.

<table>
<thead>
<tr>
<th>Cancer type</th>
<th>Surveillance recommendations</th>
</tr>
</thead>
<tbody>
<tr>
<td>Colon cancer</td>
<td>Colonoscopy (preferred) or flexible sigmoidoscopy yearly beginning at age 10-15 years. May be increased to every 6 months based on clinical findings. If multiple adenomas found, discuss timing of colectomy. Surveillance after a colectomy varies depending on type of surgery.</td>
</tr>
<tr>
<td>Small intestinal (duodenal) and stomach</td>
<td>Yearly upper endoscopy (EGD), beginning around age 20-25.</td>
</tr>
<tr>
<td>Thyroid cancer</td>
<td>Yearly thyroid examination, beginning in late teens. Consider repeating ultrasound every 2-5 years and if abnormal consider referral to specialist.</td>
</tr>
<tr>
<td>Medulloblastoma (brain cancer)</td>
<td>Yearly physical examination.</td>
</tr>
</tbody>
</table>
Abdominal desmoids | If personal history of symptomatic desmoids, consider abdominal imaging with MRI with and without contrast or CT with contrast at least annually. Symptoms should prompt immediate abdominal imaging.

Small bowel polyps and cancer | Consider small bowel imaging.

Hepatoblastoma (liver cancer) | Consider abdominal physical examination, ultrasound, and measurement of AFP blood marker every 3-6 months during the first 5 years of life.

Pancreatic cancer | When applicable discuss pancreatic cancer screening guidelines with your health care provider. Screening may be individualized based on family history.

**Risk-reducing surgery options:**
The goal of risk-reducing surgery is to reduce the risk of cancer by removing healthy tissue before cancer develops. This is also called prophylactic surgery. Risk-reducing surgery does not eliminate the chance to get cancer, but it does greatly lower the chance.

- **Colectomy:** This surgery removes all or part of the colon (large intestine) to lower the risk of colon cancer. Colectomy is usually necessary once a person develops a large number of polyps that cannot be managed through colonoscopy alone. The timing of a colectomy depends upon age, number of polyps, and other factors. This surgery may also be recommended in patients that have developed colon cancer and have FAP syndrome. There are different types of procedures for removal of the colon and/or rectum which should be discussed with a gastroenterologist and specially trained surgeon. Most colectomy operations do not require a permanent external bag.

**Medications (Chemoprevention):**
In some cases, medication may be prescribed to lower the chance of developing cancer.

- **Sulindac:** Some research shows that an NSAID called sulindac may stop colon polyps from growing. However, there is still much to be learned about the use of sulindac in people with FAP syndrome, and it may or may not be right for you. The use of sulindac is not appropriate for everyone and should not be taken without talking to your healthcare providers first.

**Who should I see for my medical care?**
It is important to find health care providers you trust for long-term follow-up care. Your primary care providers may be able to provide some of this care. In some cases, you may need to see specially trained medical providers. We are happy to provide you with referrals to specialists at Mass General as needed.

**How can I live a healthy lifestyle to lower my risk of developing cancer?**
Everyone should follow a healthy lifestyle, but this may be even more important for someone with an increased risk of cancer. According to the American Cancer Society, a healthy lifestyle includes:

- Avoiding tobacco.
- Maintaining a healthy weight.
- Participating in regular physical activity.
- Keeping a healthy diet with plenty of fruits and vegetables.
- Limiting yourself to no more than 1-2 alcoholic drinks per day.
- Protecting your skin and eyes from the sun.
- Knowing your own body and medical history, your family history, and your risks.
- Having regular check-ups and cancer screening tests.

**What are the chances that my family members also have the pathogenic variant?**

- **Your children:** Each of your children has a 50% chance to inherit the normal (working) copy of the APC gene and a 50% chance to inherit the APC gene pathogenic variant (the non-working copy). Given that colonoscopy screening begins at an early age, you should consider genetic testing for your children by age 10-15 years.
• **Your siblings and other relatives:** In most cases, brothers and sisters of a person with an *APC* gene pathogenic variant have a 50% chance to have the same pathogenic variant. Additionally, other family members (such as parents, cousins, aunts, uncles) may also be at risk to have the pathogenic variant.
  
  o Up to 20% of individuals with FAP have a *de novo* (or “new”) pathogenic variant, meaning that they are the first in the family to have the pathogenic variant. Siblings of individuals who have a *de novo* pathogenic variant have only a small risk to have the *APC* pathogenic variant. However, even if a *de novo* pathogenic variant is suspected, genetic counseling and testing is still recommended for siblings.

• **Family planning:** People with an *APC* gene pathogenic variant may have concerns about passing the gene pathogenic variant to a child. There are reproductive options that can be used to lower the chance of passing this pathogenic variant to a child. If you are interested in learning more about these options, please contact your genetic counselor for a referral.

The letter you received from your genetic counselor will give more specific recommendations about which relatives are candidates for genetic testing. However, please feel free to contact us with any further questions.

**Where can I find additional information?**

Feel free to contact us if you have any questions or would like additional resources. Some people find it useful to speak with other people with FAP syndrome who have similar concerns. We would be happy to arrange this for you if you are interested.

Glossary of cancer genetics terms:
- Cell: The basic structural and functional unit of any living thing. Each cell is a small container of chemicals and water wrapped in a membrane. The human body is made up of 100 trillion cells forming all parts of the body such as the organs, bones, and blood.
- DNA: Deoxyribonucleic acid, or DNA, is the genetic material that is passed on from parent to child, which gives the instructions for how our bodies develop, grow, and function on a daily basis.
- Early detection: The process of finding cancer when it is just starting to develop.
- Gene: A gene is a small piece of DNA that gives instructions for a specific trait.
- Inherited trait: A character or feature that is passed on from a parent to a child.
- Lifetime cancer risk: The chance that a person will develop cancer in his or her life. This is sometimes defined as the chance of developing cancer by the age of 75 or 80.
- Pathogenic variant: A change in a gene that prevents it from working correctly. Also called mutation.
- Risk-reducing surgery: Surgery to remove healthy tissue or organs before cancer develops. Also called prophylactic surgery.
- Surveillance: Screening tests or procedures to look for early signs of cancer development or cancer returning (recurrence).
- Syndrome: A set of signs and symptoms that appear together and characterize a disease or medical condition.
- Tumor suppressor gene: When working correctly, tumor suppressor genes prevent cancers from developing by controlling the growth of cells.
