and for the Healey ALS Platform Trial Study Group

Current therapeutic development in amyotrophic lateral sclerosis (ALS) relies on individual randomized clinical trials to test a specific investigational product in a single patient population. This approach has intrinsic limitations, including cost, time, and lack of flexibility. Adaptive platform trials represent a novel approach to investigate several interventions for a single disease in a continuous manner. Already in use in oncology, this approach is now being employed more often in neurology. Here, we describe a newly launched platform trial for ALS. The Healey ALS Platform Trial is testing multiple investigational products concurrently in people with ALS, with the goal of rapidly identifying novel treatments, biomarkers, and trial endpoints.

Design and Statistical Innovations in a Platform Trial for Amyotrophic Lateral Sclerosis

Merit Cudkowicz, MD, MSc ^{6,7} Sabrina Paganoni, MD, PhD,^{6,7,9} Eric A. Macklin, PhD,^{4,5}
for the HEALEY ALS Platform Trial Study Group

Platform trials allow efficient evaluation of multiple interventions for a specific disease. The HEALEY ALS Platform Trial is testing multiple investigational products in parallel and sequentially in persons with amyotrophic lateral sclerosis (ALS) with the goal of rapidly identifying novel treatments to slow disease progression. Platform trials have considerable operational and statistical efficiencies compared with typical randomized controlled trials due to their use of shared infrastructure and shared control data. We describe the statistical approaches required to achieve the objectives of a platform trial in the context of ALS. This includes following regulatory guidance for the disease area of interest and accounting for potential differences in outcomes of participants within the shared control (potentially due to differences in time of randomization, mode of administration, and eligibility criteria). Within the HEALEY ALS Platform Trial, the complex statistical objectives are met using a Bayesian shared parameter analysis of function and survival. This analysis serves to provide a common integrated estimate of treatment benefit, overall slowing in disease progression, as measured by function and survival while accounting for potential differences in the shared control group using Bayesian hierarchical modeling. Clinical trial simulation is used to provide a better understanding of this novel analysis method and complex design.

Educational Webinar

UNDERSTANDING STATISTICAL AND CLINICAL SIGNIFICANCE

SPEAKERS

JINSY ANDREWS, MD, MSC
COLUMBIA UNIVERSITY

CHRISTINA FOURNIER, MD, MSC
EMORY UNIVERSITY

ERIC MACKLIN, PhD
HARVARD MEDICAL
SCHOOL

What do researchers and scientists mean when they describe a study as “statistically significant?” How do people with ALS and clinicians understand whether or not a treatment option is “clinically significant?” This webinar and panel discussion will provide a framework for understanding the results of ALS clinical trials, using several recent studies as examples.
